Agronomy and Pest Management Research Results for Dry Edible Beans 2016

This report is a compilation of agronomy and pest management research results in dry edible beans at Ridgetown College and the Huron Research Station for 2016. It has been produced as a reference for growers and industry personnel.

A number of the pesticides that are included in this report are not currently registered for use in dry edible beans in Ontario. Always follow label directions when applying pesticides.

20% or more above average

2016 Weather

Heat unit accumulation was above average in 2016, particularly in September/October. A killing frost occurred on October 28. Above average heat in September and dry conditions resulted in rapid maturity and early harvest of studies at the Huron Research Station.

The Ridgetown Campus site had below average precipitation for 2016 – particularly May, June August and October. The Huron Research Station had average precipitation for the growing season, but monthly distribution fluctuated. May, June and September were dry, while August was very wet. Planting progress was steady in May and June, with few delays. There was little noticeable drought stress at the Huron Research Station. At Auburn, rainfall totals were much lower, and drought stress was present in August and September.

EXECUTIVE SUMMARY

Variety Registration and Performance Trials (ongoing)

Four studies were seeded in 2016 - on schedule at Auburn (June 3) but delayed at Exeter (June 14). The Exeter site had minor damage from excess rainfall throughout the season, which increased the CV. Canopy growth was good at both sites. A very dry August reduced the yield of the early maturing cultivars at Auburn.

<u>Summary of Registration/Performance Trials, Huron Research Station, 2016</u>					
Location	Market Class	Average Yield	C.V.	Notes	
Auburn	White	2991	9.4	Early cultivars affected by August drought	
Exeter	White	3081	9.0	Minor damage from excess rain	
Exeter	Cran/Kidney	2893	11.6	Minor damage from excess rain	
Exeter	Black/Pinto/SR	3360	10.5	Acceptable trial	

Preliminary Yield Trials (ongoing)

Four studies were seeded in 2016 at Auburn, Exeter and Woodstock. A preliminary site was also seeded at Emo in northern Ontario. The Woodstock site was damaged by extreme drought, which resulted in a high CV (22.4).

A number of public and private breeding programs took part in the trials, including ADM, Agr. Canada/U of G, AmeriSeed (Co-op), Cooks, Cornell, Gen-Tec, HDC, Hyland, MSU, NDSU, Pro-Vita, Secan and Seminis. The primary site was at Exeter, and these trials were repeated at Auburn (narrow row) and Woodstock (wide row).

There were 59 entries tested. Entries by market class are as follows: navy (15 entries), DRK (4 entries), LRK (8 entries), WK (2 entries), Cran (7 entries), Black (12 entries), Otebo (3) Pinto (2) and Small Red (4). The food-type soybean and Pink classes had 1 entry each.

<u>Summary of Preliminary Yield Trials, Huron Research Station, 2016</u>					
Location	Market Class	Average Yield	C.V.	Notes	
Auburn	Navy/Black/Misc	3167	10.8	Early cultivars affected by August drought	
Exeter	Navy/Black/Misc	2295	10.6	Minor damage from excess rain	
Exeter	Cran/Kidney/Misc	2524	11.7	Minor damage from excess rain	
Woodstock	Cran/Kidney/Misc	1126	22.4	Poor yield from severe drought	
Total Entries		59 distinct entries at 4 sites			

Black – Top yielding lines include Zorro, ADM B0040613 and ACUG 15-B4 .

Navy – Top yielding lines include Apex, AmeriSeed NA12062 and Mist.

Samurai (otebo), K11306 (DRK), Clouseau (LRK) and C1017332 (Cran) did well at both sites

Adzuki Variety Trial (Year 1 of 2)

The agronomic performance of Erimo adzuki bean was compared to two dry beans (Rexeter navy and Zorro black) and two food type soybeans (S03-W4 and S07-M8). Trials were planted in 2016 at Exeter, Woodstock and Winchester, but the Woodstock site was lost due to severe drought. Erimo had the lowest yield at Exeter and Winchester. However, Erimo suffered from an unidentified leaf blight at the Exeter site.

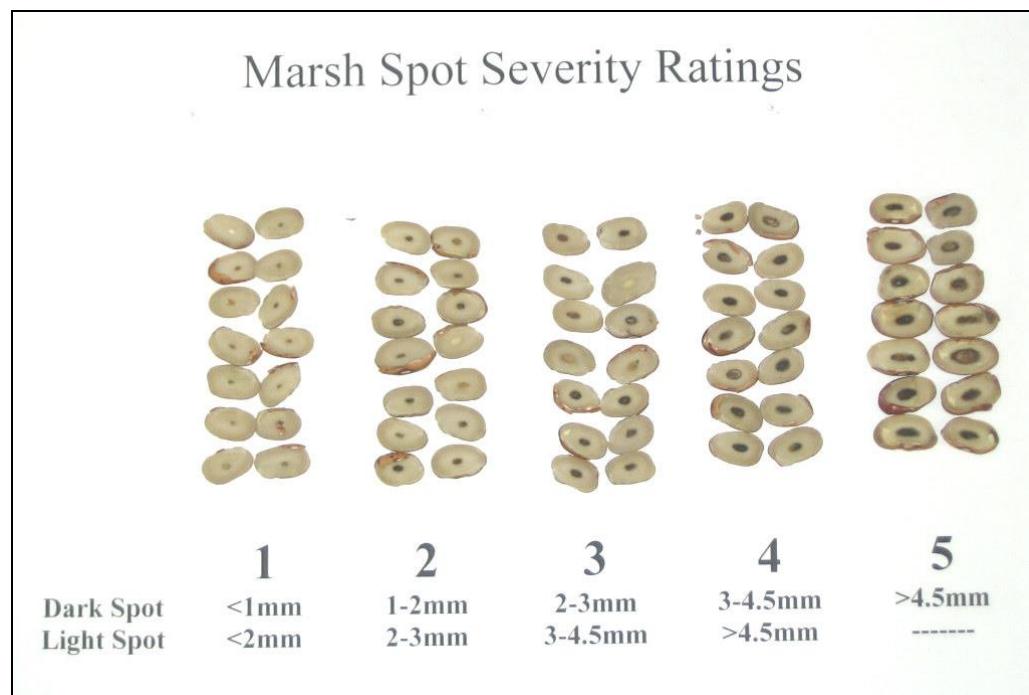

Evaluation of Marsh Spot in Dry Beans (Ongoing)

Background - Marsh spot is a physiological disorder found primarily in cranberry beans (occasionally in kidney beans). Cells in the centre of the cotyledons die and turn a gray/black colour (see Fig. 1). The damage is evident once the seed is split along the cotyledonary axis, and opened up to view the interior of the cotyledons. Marsh spot can create serious marketing issues for bean dealers. Marsh spot incidence was above average in 2016.

Registration/Performance Trials - Cranberry cultivars from trials at Exeter, Elora and St. Thomas locations were evaluated for marsh spot and compared to Etna (resistant check) and Messina (susceptible check). All of the lines tested were similar to the resistant check Etna except ACUG 15-C1 and Vero. This is the 2nd year that these two cultivars have tested high for marsh spot.

Preliminary Yield Trials – Cranberry cultivars from trials at Exeter and Woodstock were evaluated. All the lines tested were similar to the resistant check Etna except Vero.

Figure 1: Marsh Spot Severity Ratings

Anthracnose Foliar Fungicide (ongoing)

This is an ongoing study to develop a long term data set on anthracnose fungicide efficacy and economic returns. A spore suspension was used to inoculate disease free plants at the end of July. Disease pressure following inoculation was well below average for the early planted study, and very low for the late planted study. Few treatment differences were recorded in the early planted study. Fluopyram and Vertisan had relatively high disease severity, but there were no treatment differences for % pick or yield.

White Mold Foliar Fungicide (ongoing)

This is an ongoing study to develop a long term data set on white mold fungicide efficacy and economic returns. Two trials were planted in 2016. Disease pressure was low in the early planted study and very low in the late planted study. There were no treatment differences for disease incidence and severity, % pick or yield.

White Mold Fungicide Time of Day (Year 3)

Two trials were planted in 2016. Allegro 500F was applied at 6:00 AM, 12:00 PM, 6:00 PM and 12:00 AM to determine if time of day impacted fungicide performance. Disease pressure was very low in both studies. Minor differences in disease incidence and severity were measured, but this did not result in differences in % pick or yield in either study.

White Mold Cultivar x RowWidth x Population (Year 1)

One trial was planted in 2016. Overall, disease pressure was low. Two cultivars (Merlot SRM and Beryl GN) were seeded in 2 row widths (38 and 76 cm) at four populations (100, 80, 60 and 40%, with 100% population target of 200,000 plants/ha in narrow rows and 175,000 plants/ha in wide rows). Narrow rows had almost twice as much disease versus wide rows. Merlot had higher disease severity than Beryl, but this was influenced by population, as Merlot had more disease than Beryl at 100, 80 and 60% populations but not at 40%. However, differences between treatments had no effect on % pick and yield.

Root Rot Seed Treatment (ongoing)

This is an ongoing study to evaluate Cruiser Maxx Bean (current standard) with and without Dynasty or Sedaxane. This treatment was compared to Rancona Summit and Evergol Energy. All plots received Cruiser to minimize any confounding effects from soil insects.

Fusarium – disease pressure was severe, with treatment differences evident for emergence and plant vigour for the first 22 days after planting. The best seed treatments had 100-200% higher yield than the inoculated control. Cruiser Maxx Bean had very weak emergence and vigour, and low yield. The addition of Dynasty or Sedaxane to Cruiser Maxx Bean had a neutral to negative effect. Rancona Summit and Evergol had the highest emergence and vigour – typically twice as high as Cruiser Maxx Bean. This resulted in yield increases of 500-800 kg/ha for Rancona Summit versus Cruiser Maxx Bean. The addition of Sedaxane to Rancona Summit increased emergence and vigour, but did not impact yield.

Rhizoctonia – disease pressure was severe in both studies. Treatment differences were evident for emergence and plant vigour for the first 22 days after planting. The best seed treatments had 1-2X higher yield than the inoculated control. Cruiser Maxx Bean had very weak emergence and vigour, and low yield. The addition of Dynasty or Sedaxane to Cruiser Maxx Bean had no effect on plant emergence and vigour, or seed yield. Rancona Summit and Evergol had the highest emergence and vigour – usually twice as high as Cruiser Maxx Bean. This resulted in yield increases of 400-600 kg/ha. The addition of Sedaxane to Rancona Summit increased emergence and vigour, but did not impact yield.

Common Bacterial Blight (CBB) Foliar Control

Four trials were planted in 2016, using two bean market classes (navy and kidney) and two disease inoculation methods (infected seed and foliar inoculum). Three experimental compounds (Copper I, Copper W and XX) were compared to Parasol and SaniDate. Two products (XX and Sanidate) showed promise in previous work done at the University of Nebraska.

The foliar inoculated trials had very low disease pressure and no differences in disease severity,

% pick or seed yield. The seed inoculated trials had low disease pressure which resulted in slight differences in disease severity – generally all treatments had less disease than the inoculated control. These treatment differences did not result in a yield response.

AgTiv/Myconate in Dry Bean (Year 1 of 2)

AgTiv is a mycorrhizae inoculant product produced by Premier Tech, while Myconate is a chemical stimulant for mycorrhizae produced by Plant Health Care. Both products were evaluated in a small plot agronomic study at the Huron Research Station, in a small plot root rot study at Harrow Research Station and in grower strip plots in Huron and Perth counties.

At the Huron Research Station, AgTiv and Myconate were evaluated at a 1X and 2X rate alone, and together at a 1x rate. All treatments were applied along with 2.5 l/ha of 6-24-6 fertilizer at planting. There were no treatment differences for plant emergence, vigour, height, stage of development or dry weight. At harvest, there were no treatment differences for plant maturity, lodging, yield, seed weight or % pick.

2016 Navy Bean Registration and Performance Trial - Auburn

Trial Summary

Design: RCBD
Row Width: Narrow = 30 inch (76 cm)
Number of Rows Per Plot: 2
Number of Rows Harvested Per Plot: 2
Plot Length: 6 m
Harvest Length: 4m
Seeding Rate: 20 seeds/m
Seed Treatment: CruiserMaxx + Dynasty

Fertilizer: 10-40-40 actual kg/ha applied in spring
Herbicide: ppi: Pursuit 0.2 L/ha, Frontier 0.9 L/ha
post: Basagran 2.25 L/ha, Excel Super 0.67 L/ha
Planting Date: June
Fungicide: Allegro 1 L/ha, Quadris 0.5L/ha
July , Aug
Harvest Dates: September

Trial Summary

Design: RCBD

Cultivar: T9905 Navy

Row Width: 15 inch (38 cm)

Planting Date: May 25th

Number of Rows Per Plot: 4

Herbicide: May 14-Pursuit (170ml/ha) and Dual 2 Magnum (1.7L/ha) PPI

Number of Rows Harvested Per Plot: 4

Inoculation Date: July 26

Plot Length: 6m

Treatment Date: July 26, Aug 8

Harvest Length: 4m

Harvest Date: September 1

Seeding Rate: 20 seeds/m

Conclusions:

* leaf and pod disease severity in the infected control was much below average

* most treatments had low disease severity for leaf and pod ratings

* Fluopyram (Trt 10), Vertisan (trt 13) and Acapela (Trt 14) had higher leaf and pod disease severity compared to the other treatments

* there were no differences between treatments for pick, yield or yield-pick

Means followed by same letter do not significantly differ (P=.05, LSD)

Planted: June 10th 6 rows @ 38 cm and 6 meter length.

Harvested: September 9th 4 rows @ 38 cm and 4 meter length.

Design: RCBD with 4 replications.

Inoculum: White mold inoculum applied foliarly

Treatments: 1st application on July 27th at 6:00 AM, temperature=17.5 C, RH=93%, Wind=1 kph S, dew present, soil damp

Treatments: 2nd application on August 9th at 6:30 AM, temperature=16 C, RH=75%, Wind=3.5 kph SE, dew present, soil damp

Herbicide : Pursuit @ 200 ml/ha Dual 2 Magnum @ 1.7 L/ha (May 23rd)

Irrigation: July 26th, 29th, August 4th, 8th, 10th, 24th, September 2nd.

Conclusions:

*no phytotoxicity was measured from fungicide application

* disease severity in the untreated check was very low, compared to past work.

* there were no treatment differences for disease incidence or severity, seed weight or seed yield.

* Allegro, Acapela, Priaxor+Lance, and Double Nickel LC had less pick than the Untreated Control.

Planted: May 25 2016 6 rows @ 38 cm and 6 meter length.

Harvested: October 5 4 rows @ 38 cm and 4 meter length.

Design: RCBD with 4 replications.

Inoculum: White mold inoculum applied foliarly

Treatments: 1st application on July 27 at 8:30 AM, temperature=20 C, RH=89%, Wind=4 kph S, dew present, soil damp

Treatments: 2nd application on August 9 at 8:00 AM, temperature=19 C, RH=72%, Wind=3.5 kph E, dew present, soil damp

Herbicide : Pursuit @ 170 ml/ha Dual 2 Magnum @ 1.7 L/ha May 23

Irrigation: July 26, August 4, 8, 10, 24, September 2.

Conclusions:

- * no phytotoxicity was measured from fungicide application
- * disease severity in the untreated check was moderate.
- * top treatments were #2 (Acapela) #6 (Stratego Pro) #9 (BAS793F) and #10 (Priaxor +BAS793F)
- * two applications of Stratego Pro (trt 6) did not impact on disease severity, compared to one application (trt 5)
- * Allegro and Priaxor had similar yield as the untreated control

Planted: June 2 2 rows @ 76 cm and 2 meter length.

Harvested: September 12 2 rows @ 76 cm and 2 meter length.

Design: RCBD with 4 replications.

Inoculum: Fusarium solani applied in the seed furrow at planting, at a rate of 5 grams per meter of row

Herbicide : Pursuit @ 200 ml/ha (May 23) Bonanza @ 1.5 L/ha (May 23) Glyphosate 2L/ha (September 2)

Insecticide: Matador @ 83 ml/ha (July 19, August 3)

Fungicide: Allegro @ 1 L/ha (Aug 3)

Conclusions:

- * differences in emergence and vigour between the two control trts were measured for 22 days after planting, which suggests that the inoculum gave some disease pressure
- * Cruiser Maxx Bean (trt 3,4,5,6) had weaker emergence, vigour and yield than all other seed treatments tested
- * Rancona Summit + Sedaxane (trts 8 and 9) had the highest emergence and vigour and were better than most other treatments for the first 22 days after planting.
- * the addition of Dynasty (trt 4) to Cruiser Maxx Bean (trt 3) reduced emergence and vigour
- * the addition of Sedaxane (trt 5 and 6) to Cruiser Maxx Bean (trt 3) reduced emergence but had no effect on vigour
- * the addition of a Sedaxane (trts 8 and 9) to Rancona Summit (trt 7) increased emergence but had little effect on vigour
- * Emergence, vigour or yield were not influenced by a high rate of Sedaxane (trt 6 and 9) versus a low rate of Sedaxane (trts 5 and 8)
- * no treatment differences in seed weight were measured
- * Rancona Summit (trt 7,8,9) and Evergol (trt 10) had the highest yield
- * Cruiser Maxx Bean (trt 3,4,5,6) yield was similar to the uninoculated control

Means followed by same letter do not significantly differ (P=.05, LSD)

Notes:

* Uninoculated control was treated with Parasol (1500 g ai/ha) every 2 weeks

Planting Date: May 24, 2016

Harvest Date: September 1, 2016

Cultivar: T9905 (navy)

Innoculation Dates: July 20 and 21

Conclusions:

* disease development was poor, compared to past experiments

* there were no treatment differences for disease severity of leaf or pod tissue

* there were no treatment differences for seed weight, seed yield or pick

* treatment differences occurred for yield-pick, but could not be substantiated by differences in disease scores

Abstract

Only one herbicide mode of action (ALS inhibitor) is currently available to Ontario dry bean producers for soil-applied broadleaf weed control. Four field studies were conducted over two years (2014, 2015) to examine the tolerance of four market classes of dry beans to sulfentrazone (210 and 420 g·ai·ha⁻¹) and pyroxasulfone (100 and 200 g·ai·ha⁻¹) applied alone and in combination. The registration of these two herbicides would provide Ontario dry bean producers with two additional modes of action for broadleaf weed control. Pyroxasulfone caused up to 23%, 6%, 7% and 10% injury in adzuki, kidney, small red Mexican and white bean, respectively; sulfentrazone caused up to 51%, 12%, 15% and 44% injury and the combination caused up to 90%, 23%, 29% and 62% injury, respectively. Kidney and small red Mexican bean density, height, seed moisture content and yield were not affected. Pyroxasulfone (200 g·ai·ha⁻¹) + sulfentrazone (420 g·ai·ha⁻¹) reduced adzuki and white bean density, shoot dry weight, height and yield. This study concludes that pyroxasulfone (100 g·ai·ha⁻¹) + sulfentrazone (210 g·ai·ha⁻¹) applied PRE can be safely used to control weeds in Ontario kidney and small red Mexican bean production.

Abstract

Ontario dry bean (*Phaseolus vulgaris* L.) growers have few options for broadleaf weed control. Sulfentrazone is a group 14 herbicide that provides good control of several common Ontario weed species, and would provide another mode of action for broadleaf weed control if registered for use in Ontario dry beans. Five field studies were conducted during 2014 and 2015 to determine if a low dose of imazethapyr added to a tank mix of sulfentrazone + s-metolachlor would improve broadleaf control in white bean. Sulfentrazone (140 and 210 g·ai·ha⁻¹) was mixed with imazethapyr and s-metolachlor and evaluated at 2 and 4 weeks after crop emergence for crop injury. Weed control was assessed visually at 4 and 8 weeks after herbicide application (WAA), and weed stand counts and biomass were determined at 8 WAA. Seed moisture and yield were determined at harvest. At 8 WAA, sulfentrazone (140 g·ai·ha⁻¹) controlled pigweed species, common ragweed, common lambsquarters, wild mustard, barnyard grass and green foxtail 100%, 4%, 100%, 2%, 86% and 62%, respectively. The addition of imazethapyr (37.5 g·ai·ha⁻¹) to sulfentrazone (140 g·ai·ha⁻¹) improved the control of common ragweed, wild mustard and green foxtail by 19%, 98% and 33%, respectively. The three-way tank mix of sulfentrazone (140 g·ai·ha⁻¹) plus s-metolachlor (1050 g·ai·ha⁻¹) plus imazethapyr (37.5 g·ai·ha⁻¹) controlled pigweed species, common ragweed, common lambsquarters, wild mustard, barnyard grass and green foxtail 100%, 35%, 100%, 100%, 96% and 100%, respectively. The tank mixes evaluated caused unacceptably high levels of crop injury; this study does not support the registration of sulfentrazone plus s-metolachlor + imazethapyr for use in Ontario white bean.

Sulfentrazone tank mix partners for weed control in white bean (*Phaseolus vulgaris* L.)

Allison N. Taziar, Nader Solani, Christy Shropshire, Darren E. Robinson, Mitch Long,
Chris L. Gillard, and Peter H. Sikkema

Abstract: Soil-applied broadleaf herbicides for weed management in dry beans (*Phaseolus vulgaris* L.) in Ontario are limited. Sulfentrazone is an effective broadleaf herbicide with some grass activity and is currently registered for use in soybean and some pulse crops in Canada. If registered for use in dry beans in Ontario, sulfentrazone would provide growers with another mode of action for broadleaf weed control. Five field studies were conducted over a two year period (2014–2015) to determine the tolerance of white beans to sulfentrazone applied pre-emergence (PRE) and if the spectrum of weeds controlled can be expanded by tank-mixing sulfentrazone with a soil-applied grass herbicide. Sulfentrazone (140 and 210 g ai ha⁻¹) was mixed with pendimethalin, dimethenamid-p, s-metolachlor or pyroxasulfone. All the tankmixes evaluated provided good control of green foxtail (*Setaria viridis* L.), pigweeds (*Amaranthus powelli* L. and *A. retroflexus* L.), and common lambsquarters (*Chenopodium album* L.), but only sulfentrazone + pendimethalin had an adequate margin of crop safety. Based on this study, sulfentrazone combined with a grass herbicide provides acceptable control of some grass and broadleaf weed species; however, further research is required to determine if there is an adequate margin of crop safety for weed management in Ontario dry beans.

Key words: biomass, density, Injury, height, navy bean, *Phaseolus vulgaris* L.

Résumé : Le nombre d'herbicides que l'on peut épandre sur le sol pour lutter contre les dicotylédones dans les champs de haricot (*Phaseolus vulgaris* L.) est restreint en Ontario. Le sulfentrazone fonctionne bien contre les dicotylédones et certaines graminées. Il est homologué pour le soja et quelques légumineuses au Canada. S'il était homologué pour le haricot en Ontario, les producteurs auraient une corde de plus à leur arc pour lutter contre les dicotylédones. Les auteurs ont procédé à cinq études sur le terrain pendant deux ans (2014, 2015) afin de vérifier la tolérance du haricot blanc au sulfentrazone appliqué avant la levée et pour déterminer si on pourrait élargir la gamme de dicotylédones contrôlées en y ajoutant un herbicide contre les graminées. Le sulfentrazone (140 et 210 g de matière active par hectare) a été mélangé à du pendiméthalin, du diméthénamide-p, du s-métolachlor ou de la pyroxasulfone. Tous ces mélanges contrôlent bien la sétaire verte (*Setaria viridis* L.), les amaranthes (*Amaranthus powelli* L. and *A. retroflexus* L.) et le chénopode blanc (*Chenopodium album* L.), mais seul celui de sulfentrazone et de pendiméthalin présente une marge de sécurité suffisante pour la culture. D'après les résultats de cette étude, mélanger le sulfentrazone à un herbicide à graminées permet de combattre de façon acceptable certaines graminées et dicotylédones. Cependant, il faudrait entreprendre des recherches plus poussées pour savoir si la marge de sécurité est suffisante en vue de l'utilisation d'un tel mélange pour désherber chimiquement les champs de haricot en Ontario. Studies were conducted in Ontario dry bean (*Phaseolus vulgaris* L.) in 2010 and 2011 using fulvic acid (LX7®, MTS Environmental Inc.) or humic acid (Plant XL®, Alpha-Agri) fertilizers. Twenty fulvic acid field trials and 15 humic acid field trials indicate that these fertilizers were ineffective as plant vigour, height, 100-seed weight, and yield were similar to a control treatment.

Key words: Dry bean, *Phaseolus vulgaris*, fulvic acid, humic acid

Humic compounds, such as fulvic acid and humic acid, are formed by chemical and microbial degradation of plant and animal material and are a principal component of soil organic matter (Canellas et al. 2015). Because of their growth promoting properties in plants, humic compounds have been studied for decades (Schnitzer and Poapst 1967). In general, the application of fulvic and humic acid fertilizer amendments have been shown to enhance root growth, nutrient uptake, alleviate stress, and increase yield in various crops (Canellas et al. 2015).
